Abstract

The SPIROC chip is a dedicated very front-end electronics for an ILC prototype hadronic calorimeter with Silicon photomultiplier (or MPPC) readout. This ASIC is due to equip a 10,000-channel demonstrator in 2009.

SPIROC is an evolution of FLC_SiPM used for the ILC AHCAL physics prototype [1].

SPIROC was submitted in June 2007 and will be tested in September 2007. It embeds cutting edge features that fulfil ILC final detector requirements. It has been realized in 0.35m SiGe technology. It has been developed to match the requirements of large dynamic range, low noise, low consumption, high precision and large number of readout channels needed.

SPIROC is an auto-triggered, bi-gain, 36-channel ASIC which allows to measure on each channel the charge from one photoelectron to 2000 and the time with a 100ps accurate TDC. An analogue memory array with a depth of 16 for each channel is used to store the time information and the charge measurement. A 12-bit Wilkinson ADC has been embedded to digitize the analogue memory content (time and charge on 2 gains). The data are then stored in a 4kbytes RAM. A very complex digital part has been integrated to manage all these features and to transfer the data to the DAQ which is described on [2].

I. First Generation SiPM Readout: FLC_SiPM

The CALICE collaboration has designed an analogue HCAL prototype using Scintillating fibers read out by SiPM detectors. That 8000-channel physics prototype is currently in test beam at CERN. The read-out of that detector is ensured by an analogue front-end chip called FLC_SiPM [1]. The chip is designed in a 0.8µm CMOS technology of AMS and has an area of 10 mm² (fig. 3). Around 1000 circuits have been produced at the end of 2004 and are packaged in a QFP100 case.

An 8-bit DAC has been added at the preamplifier input to tune the input DC voltage in order to adjust individually the SiPM high voltage.
Connecting the SiPM to our chip we can clearly observe peaks for 1 photo-electron, 2 p.e., 3 p.e. and so on as shown in figure 4. The signal to noise ratio obtained for single pixel signal is about 4.

![Figure 3: SPIROC Layout](image)

**Figure 3:** SPIROC Layout

The SPIROC chip has been designed to meet the ILC hadronic calorimeter with SiPM readout [4]. The next figures (5 and 6) show an AHCAL scheme. One of the main constraints is to have a calorimeter as dense as possible. Therefore any space for infrastructure has to be minimized. One of the major requirements is consequently to minimize power to avoid active cooling in the detection gap. The aim is to keep for the DAQ-electronics located inside the detection gaps the power as low as 25 µW per channel.

The SPIROC chip is a 36-channel input front end circuit developed to read out SiPM outputs. The block diagram of the ASIC is given in Figure 8. Its main characteristics are given in Table 1.

![Figure 7: SPIROC general scheme](image)

**Figure 7:** SPIROC general scheme
C. SPIROC analogue core

Each channel includes an input DAC which allows to adjust the SiPM high voltage on 5 Volts, and consequently the detector gain.

Two variable preamplifiers allow to obtain the requested dynamic range (from 1 to 2000 photoelectrons) with a level of noise of 1/10 photoelectron.

Then, these charge preamplifiers are followed by two variable CRRC\textsuperscript{2} slow shapers (50 ns-175 ns) and two 16-deep Switched Capacitor Array (SCA) in which the analogue voltage will be stored.

A voltage 300 ns ramp gives the analogue time measurement. The time is stored in a 16-deep SCA when a trigger occurs.

In parallel, trigger outputs are obtained via fast channels made of a fast shaper followed by a discriminator. The trigger discriminator threshold is given by an integrated 1 bit DAC. This threshold is finely tuneable on additional 4 bits channel by channel. The discriminator output feeds the digital part which manages the SCA.

The complete scheme of one channel is shown on figure 8.

For the time measurement, the simulation shows a gain of 120 mV per photoelectron with a peaking time of 15 ns on the “fast channel” (preamplifier + fast shaper). The noise to photoelectron ratio is about 24 which is quite comfortable to trigger on half photoelectron.

For the energy measurement, the simulation gives a gain of 10 mV per photoelectron with a peaking time of about 100 ns on “high gain channel” (high gain preamplifier + slow shaper). The noise to photoelectron ratio is about 11 and should be sufficient for the planned application. On the “low gain channel”, the noise to photoelectron ratio is about 3 and it meets largely the requirement.

D. Embedded ADC

The ADC used in SPIROC is based on a Wilkinson structure. Its resolution is 12 bits. As the default accuracy of 12 bits is not always needed, the number of bits of the counter can be adjusted from 8 to 12 bits.

This type of ADC is particularly adapted to this application which needs a common analogue voltage ramp for the 36 channels and one discriminator for each channel. The ADC is able to convert 36 analogue values (charge or time) in one run (about 100 \(\mu\)s at 40 MHz). If the SCA is full, 32 runs are needed (16 for charges and 16 for times).

E. Expected analogue performance

The new analogue chain in SPIROC allows the single photoelectron calibration and the signal measurement to be on the same range, simplifying greatly the absolute calibration.

An analogue simulation of a whole analogue channel is shown in figure 9. It is obtained with an equivalent charge of 1 photoelectron (160 fC at SiPM gain \(10^6\)).

F. SPIROC operating modes

The system on chip has been designed to match the ILC beam structure (figure 10). The complete readout process needs at least 3 different steps: acquisition phase, conversion phase, readout phase, and possibly idle phase.

![SPIROC one channel diagram](image)

![One channel simulation](image)
**Acquisition mode:**

During the acquisition mode, the valid data are stored in analogue memories in each front-end chip during the beam train.

An external signal is available to erase the active column named “No_Trigger”. It can be used to erase the column if a trigger was due to noise.

**Conversion mode:**

Then, during the conversion mode, the data are converted into digital before being stored in the chip SRAM by following the mapping represented in [Figure 11](#).

36 charges and 36 times stored in SCA are converted for each column. When these 72 conversions are over, data are stored in the memory in order to start a new one for the next column.

The Bunch Crossing Identifier (BCID), hit (H) channels and gains (G) are also saved into RAM.

\[\begin{array}{c|c|c|c}
0 & 0 & G & H \\
0 & 0 & G & H \\
0 & 0 & G & H \\
\end{array}\]

**Readout mode:**

Finally, during the readout mode, the data are sent to DAQ during the inter-train (20kbits per ASIC per bunch train). The readout is based on a daisy chain mechanism initiated by the

**Figure 10:** SPIROC running modes

- **Acquisition mode**

- **Conversion mode**

When an event occurs:

- Charge is stored in analogue memory
- Time is stored in digital (coarse) and analogue (fine) memory
- Trigger is automatically rearmed at next coarse time flag (bunch crossing ID)

Depth of memory is 16

The data (charge and time) stored in the analogue memory are sequentially converted into digital data and stored in a SRAM.

The events stored in the RAM are readout through a serial link when the chip gets the token allowing the data transmission. When the transmission is done, the token is transferred to the next chip. 256 chips can be read out through one serial link.

**Figure 12:** Detector readout scheme

- **Idle mode**

When all these operations are done, the chip goes to idle mode to save power. In the ILC beam structure 99% of power can be saved.

The management of all the different steps of normal working (acquisition, A/D measure and read-out) needs a very complex digital part which was integrated in the ASIC [3].

**G. Power pulsing**

The new electronics readout is intended to be embedded in the detector. One important feature is the reduction of the power consumption. The huge number of electronic channels makes crucial such a reduction to 25 µWatt per channel using the power pulsing scheme, possible thanks to the ILC bunch pattern: 2 ms of acquisition, conversion and readout data for 198 ms of dead time. However, to save more power, during each mode, the unused stages are off.

**III. CONCLUSION**

The SPIROC chip has been submitted in June 2007 and will be tested in September 2007. It embeds cutting edge features that fulfil ILC final detector requirements including ultra low power consumption and extensive integration for SiPM readout.

The system on chip is driven by a complex state machine ensuring the ADC, TDC and memories control.

The SPIROC chip is due to equip a 10,000-channel demonstrator in 2009 in the frame work of EUDET.
