**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Measurement of  $\sigma_{\Lambda_b^0}/\sigma_{\bar{B}^0} \times \mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-) / \mathcal{B}(\bar{B}^0 \rightarrow D^+ \pi^-)$  in  $p\bar{p}$  Collisions at  $\sqrt{s} = 1.96$  TeV

(Dated: December 22, 2005)

We present the first observation of the baryon decay  $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$  followed by  $\Lambda_c^+ \rightarrow p K^- \pi^+$  in  $106 \text{ pb}^{-1} p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$  in the CDF experiment. In order to reduce systematic error, the measured rate for  $\Lambda_b^0$  decay is normalized to the kinematically similar meson decay  $\bar{B}^0 \rightarrow D^+ \pi^-$  followed by  $D^+ \rightarrow \pi^+ K^- \pi^+$ . We report the ratio of production cross sections ( $\sigma$ ) times the ratio of branching fractions ( $\mathcal{B}$ ) for the momentum region integrated above  $p_T > 6 \text{ GeV}/c$  and pseudorapidity range  $|\eta| < 1.3$ :  $\sigma(p\bar{p} \rightarrow \Lambda_b^0 X)/\sigma(p\bar{p} \rightarrow \bar{B}^0 X) \times \mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-)/\mathcal{B}(\bar{B}^0 \rightarrow D^+ \pi^-) = 0.82 \pm 0.08 \text{ (stat)} \pm 0.11 \text{ (syst)} \pm 0.22 \text{ (}\mathcal{B}(\Lambda_c^+ \rightarrow p K^- \pi^+)\text{)}$ .

PACS numbers: 14.20.Mr, 13.30.Eg, 14.65.Fy

Weak decays of baryons containing  $b$  quarks are a good laboratory for testing the Heavy Quark Effective Theory (HQET) [1]. The  $\Lambda_b^0$  baryon is the ground state of the  $udb$  quark system, and, in the heavy quark limit, the light degrees of freedom are in the state of zero total angular momentum [2]. Fully hadronic  $b \rightarrow c\bar{u}d$  transitions are more complicated in baryons than in mesons because there are diagrams which are not present in the decays of the latter. Various extensions of HQET have

been used to evaluate the  $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$  decay rate [3], but the predictions vary over a large range. However, in Soft Collinear Effective Theory (SCET) [4], all tree-level amplitudes can be properly evaluated, resulting in an explicit prediction for the ratio of branching fractions  $\mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-)/\mathcal{B}(\bar{B}^0 \rightarrow D^+ \pi^-) \approx 1.7$  [5]. The decays of  $\Lambda_b^0$  are also interesting because they may provide a means to determine CKM matrix elements with different systematic uncertainties than the determinations

from the decays of  $B$  mesons [6].

This is the first reconstruction of a hadronic decay of a  $b$  baryon at a hadron collider that does not use a  $J/\psi$  in the final state. In addition, our sample has more than an order of magnitude more events than any previous sample of fully reconstructed  $\Lambda_b^0$  decays, and, for the same luminosity, is about five times larger than a sample of  $\Lambda_b \rightarrow J/\psi \Lambda$  decays. Since  $b$  baryons are not produced at the  $B$  factories operating at the  $\Upsilon(4S)$  resonance, studying them comprises a unique facet of the  $B$  physics program at Collider Detector at Fermilab (CDF II) [7]. In particular, a large sample of fully reconstructed  $\Lambda_b^0$  decays would allow CDF to study other properties of  $b$  baryons, *e.g.*, to measure the lifetime of  $\Lambda_b^0$ , and also to search for decays of heavier  $b$  baryons such as  $\Sigma_b^\pm \rightarrow \Lambda_b^0 \pi^\pm$ .

This paper presents a measurement of a ratio of  $\Lambda_b^0$  and  $\bar{B}^0$  branching fractions multiplied by the ratio of production cross-sections,

$$R \equiv \frac{\sigma(p\bar{p} \rightarrow \Lambda_b^0 X)}{\sigma(p\bar{p} \rightarrow \bar{B}^0 X)} \times \frac{\mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-)}{\mathcal{B}(\bar{B}^0 \rightarrow D^+ \pi^-)}, \quad (1)$$

where the  $\sigma$  quantities are the cross-sections for  $\Lambda_b^0$  and  $\bar{B}^0$  production in the pseudorapidity range  $|\eta| < 1.3$  with momentum in the transverse plane,  $p_T$ , above 6 GeV/ $c$  [8].

The quantity  $R$  compares the branching fractions of the topologically similar, fully reconstructed decays  $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$  and  $\bar{B}^0 \rightarrow D^+ \pi^-$ , where the charmed hadrons decay via similar three-body channels  $\Lambda_c^+ \rightarrow p K^- \pi^+$  and  $D^+ \rightarrow \pi^+ K^- \pi^+$  [9]. To extract a branching ratio, a good understanding of the absolute reconstruction efficiency is needed. However, to obtain  $R$  only the ratio of the reconstruction efficiencies of two topologically and kinematically similar decay modes is evaluated, significantly reducing the systematic errors on the measured quantity.

The upgraded CDF II detector is well-suited for the detailed study of weak decays of heavy baryons. In particular, the advent of the Silicon Vertex Trigger (SVT) [10], which uses precise position measurements to select events containing weakly decaying heavy hadrons, allows CDF II to collect many hadronic decay modes of heavy baryons for the first time. This measurement is performed using a 106 pb $^{-1}$  sample of  $p\bar{p}$  collisions collected by CDF II between February 2002 and June 2003. This data sample corresponds to  $\sim 10^9$   $b$  hadron decays produced in the central detector region. A full description of the CDF II detector can be found elsewhere [7]. The detector components pertinent to this analysis are the silicon microstrip vertex detector (SVX II) [11], the drift-chamber central tracker (COT) [12] and a three-tiered trigger system (Levels 1, 2, and 3). The five double-sided layers of the SVX II used in this analysis provide up to 10 position measurements. Of these, up to five are in the  $r$ - $\phi$  [8] plane (each precise to about 15  $\mu\text{m}$ ), three are longitudinal, and two are small-angle-stereo. The  $\phi$  strips are parallel to the  $z$ -axis, longitudinal strips

are inclined at 90°, and the small-angle-stereo strips are inclined at 1.2°. The SVX II spans the radii between 2.5 and 10.6 cm, and covers the pseudorapidity range  $|\eta| < 2$ . The COT has 96 measurement layers between the radii of 40 and 137 cm. These are organized into alternating axial and small-angle-stereo (2°) super-layers. The COT has a smaller pseudorapidity coverage ( $|\eta| < 1.3$ ) than the SVX II. Both tracking detectors are immersed in a 1.41 T magnetic field parallel to the  $z$  axis.

This analysis in particular relies on the SVT, which operates as a part of the Level 2 trigger system. The trigger makes it possible to select events at a rate of  $\sim 100$  Hz from the  $\sim 1$  MHz interaction rate. The components of the three level trigger system pertinent to this measurement are the Extremely Fast Tracker (XFT) at Level 1 and the SVT at Level 2. The XFT uses four axial super-layers of the COT to find tracks with  $p_T > 1.5$  GeV/ $c$ . The SVT combines the XFT measurement with  $r$ - $\phi$  hits from the SVX II detector. The track finding is performed using a large look-up table of hit patterns. The found track candidates are fitted for curvature, angle projected onto the transverse plane and impact-parameter [13]. The impact-parameter measurement allows the selection of long-lived particles in the trigger decision.

The signal ( $\Lambda_b^0$ ) and normalization ( $\bar{B}^0$ ) events are collected using the same trigger. At Level 1, two tracks must satisfy  $p_T > 2.0$  GeV/ $c$ , a scalar sum of transverse momenta  $p_{T1} + p_{T2} > 5.5$  GeV/ $c$ , and an angular separation projected onto the transverse plane of  $\Delta\phi < 135^\circ$ . At Level 2 the transverse momentum cuts are repeated, and it is required that each track has impact parameter  $d_0 > 120$   $\mu\text{m}$ , with an angular separation between the tracks projected onto the transverse plane of ( $2^\circ < \Delta\phi < 90^\circ$ ). Finally, the distance evaluated in the transverse plane from the primary vertex to the two-track intersection point must be greater than 200  $\mu\text{m}$ .

Additional criteria are imposed on the triggered sample in order to reject as many background events as possible while keeping most of the signal. To reconstruct  $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$ , minimum acceptable COT and SVX hit requirements are imposed, and all valid four track combinations are considered. The  $p_T$  of the proton candidate from the  $\Lambda_c^+$  and the  $\pi^-$  candidate from the  $\Lambda_b^0$  must be greater than 2.0 GeV/ $c$ , which strongly favors these particles to be the two which caused the event to pass the trigger. The  $p_T$  of the proton candidate must be larger than the  $p_T$  of the  $\pi^+$  candidate from the  $\Lambda_c^+$ . The  $p_T$  of the  $\Lambda_b^0$  and  $\Lambda_c^+$  candidates must be greater than 7.5 GeV/ $c$  and 4.5 GeV/ $c$ , respectively. In Equation (1),  $\sigma_{\Lambda_b^0}$  and  $\sigma_{\bar{B}^0}$  are defined for  $p_T > 6$  GeV/ $c$ . The events in the data sample must satisfy  $p_T > 7.5$  GeV/ $c$ , and the difference is accounted for by using the Monte Carlo simulation based on the  $p_T$  distributions of both  $\Lambda_b^0$  and  $\bar{B}^0$  measured in data [14].

Each of the unstable particles ( $\Lambda_b^0$ ,  $\bar{B}^0$ ,  $\Lambda_c^+$ , and  $D^+$ ) is reconstructed by considering all valid combinations of tracks and requiring them to satisfy the decay hypothe-

sis. The charmed hadrons  $\Lambda_c^+$  and  $D^+$  are reconstructed first: each triplet of tracks that satisfies the selection criteria (detailed below) is constrained to pass through the same point, called the decay vertex. The decay vertex is determined by varying the track parameters of the stable daughters within their uncertainties to minimize the  $\chi^2$ . The  $\Lambda_c^+(D^+)$  candidate is then combined with a fourth track to form a  $\Lambda_b^0(\bar{B}^0)$  candidate. The full topology of the decay is then imposed in another kinematic fit, resulting in a simultaneous measurement of the  $\Lambda_b^0(\bar{B}^0)$  and  $\Lambda_c^+(D^+)$  vertices.

Using these measurements, the reconstructed invariant mass of the  $\Lambda_c^+$  must be between  $2.269 \text{ GeV}/c^2$  and  $2.301 \text{ GeV}/c^2$ . Other selection criteria rely on  $L_{xy}$ , the projection onto the  $x$ - $y$  (transverse) plane of the decay length measured from the production vertex to the decay point; the production vertex is estimated by the position of the beamline averaged over each run calculated for the  $z$  coordinate of the secondary vertex. A product of the proper decay time and the speed of light,  $ct$ , is also used. It is derived from  $L_{xy}$ :  $ct = (\vec{L}_{xy} \cdot \hat{p}_T)(mc/p_T)$ , where  $\vec{L}_{xy}$  is the decay vector of  $\Lambda_b^0(\bar{B}^0)$  projected onto the  $x$ - $y$  plane,  $p_T$  is the transverse momentum,  $\hat{p}_T$  is the unit vector in the direction of the transverse momentum, and  $m$  is the world average mass of the  $\Lambda_b^0(\bar{B}^0)$ . In order to suppress the combinatorial background from the interaction point, we impose  $ct(\Lambda_b^0) > 225 \mu\text{m}$  (compared to the  $b$  baryon mean decay length of  $368 \pm 24 \mu\text{m}$  [15]). Calculated relative to the  $\Lambda_b^0$  decay point,  $ct(\Lambda_c^+)$  must be  $ct(\Lambda_c^+) > -65 \mu\text{m}$ . For a true  $\Lambda_c^+$ , a small negative  $ct$  may arise due to resolution effects; on the other hand, the  $ct(\Lambda_c^+)$  of combinatorial background candidates may have large negative values. The distance of closest approach in the transverse plane of the trajectory of the  $\Lambda_b^0$  candidate to the primary vertex must be less than  $85 \mu\text{m}$ . The  $\chi_{xy}^2$  of the  $\Lambda_b^0$  and  $\Lambda_c^+$  kinematic fits are required to be less than 30 and 20 respectively, where  $\chi_{xy}^2$  is a  $\chi^2$ -like goodness-of-fit quantity using only the track parameters in the transverse plane.

The normalization mode ( $\bar{B}^0 \rightarrow D^+\pi^-$ ) is reconstructed using selection criteria identical to those of the signal mode, except for a different invariant mass requirement for the  $D^+$  candidate and no analogy to the  $p_T(p) > p_T(\pi^+)$  cut. The  $D^+$  candidate invariant mass must be between  $1.848 \text{ GeV}/c^2$  and  $1.888 \text{ GeV}/c^2$ . The distributions of the invariant mass of  $\Lambda_b^0 \rightarrow \Lambda_c^+\pi^-$  and  $\bar{B}^0 \rightarrow D^+\pi^-$  candidates are shown in Figures 1 and 2, respectively.

Figure 1 shows the binned likelihood fit to the invariant mass distribution of  $\Lambda_b^0$  candidates. The large Gaussian peak at  $5.6 \text{ GeV}/c^2$  is the signal. The dash-dotted curve corresponds to the exponential combinatorial background. This component is constrained by the data in the invariant mass region above the  $\Lambda_b^0$  mass. The small asymmetric peak at  $5.5 \text{ GeV}/c^2$  (solid line) corresponds to contributions from fully reconstructed  $B$ -meson decays resulting in a final state with four tracks, where at least one track is misidentified. This shape is obtained

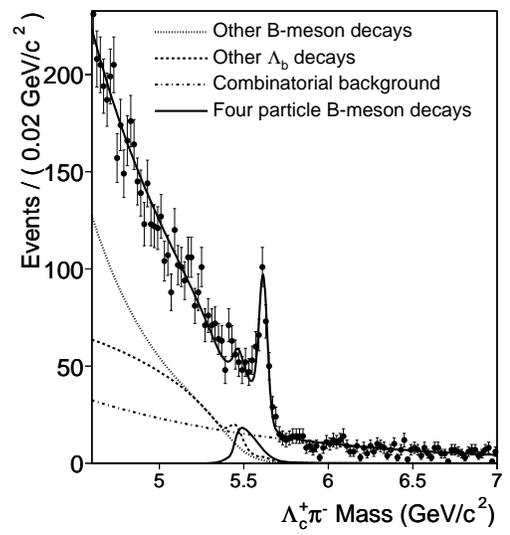

FIG. 1:  $\Lambda_b^0 \rightarrow \Lambda_c^+\pi^-$  yield with binned likelihood mass fit. The background shapes are defined in the text.

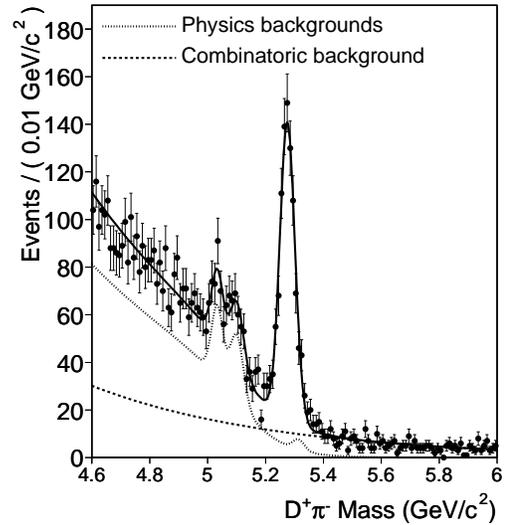

FIG. 2:  $\bar{B}^0 \rightarrow D^+\pi^-$  yield with binned likelihood fit. The background shapes are defined in the text.

using a full detector simulation of these modes. It is consistent with the shape of  $\bar{B}^0 \rightarrow D^+\pi^-$  candidates found in the  $\Lambda_b^0$  sample. The dotted and dashed curves correspond to all the other  $B$ -meson and  $\Lambda_b^0$  backgrounds, respectively. These shapes are determined from a large parametric Monte Carlo sample which includes all known decays of  $B^+$ ,  $B^0$ , and  $B_s$  and  $\Lambda_b^0$  hadrons. Finally, there is a very small Gaussian distribution (not shown) from the Cabibbo-suppressed mode  $\Lambda_b^0 \rightarrow \Lambda_c^+K^-$  (fixed to an expected 8% of the signal yield [16]). The total distribution is  $F_{\text{tot}} = G_{\text{signal}} + E_{\text{comb}} + F_{\text{four-track}} + F_{\text{other-B}} + F_{\text{other-}\Lambda_b^0} + G_{\Lambda_c^+K^-}$ , where  $G$  indicates a Gaussian distribution,  $E$  indicates an exponential, and  $F$  indicates a

more complicated functional form.

In the fit, the width of  $\Lambda_b^0$  signal is fixed to  $26.4 \text{ MeV}/c^2$ , obtained by scaling the  $\bar{B}^0$  width in data by the ratio of widths from the Monte Carlo simulation. The relative contribution of each background type in the fit is guided by two constraints: the first describes the normalization of  $F_{\text{four-track}}$  relative to  $F_{\text{other-B}}$  (*i.e.*,  $N_{\text{four-track}}/N_{\text{other-B}}$ ), where  $N$  is number of events; the second describes the normalization of  $F_{\text{other-}\Lambda_b^0}$  relative to  $(F_{\text{other-B}} + F_{\text{four-track}})$ , (*i.e.*,  $N_{\text{other-}\Lambda_b^0}/(N_{\text{four-track}} + N_{\text{other-B}})$ ). The value of each constraint is inferred from the relative abundance of the background types in the large parametric Monte Carlo sample. The value of the  $(N_{\text{four-track}}/N_{\text{other-B}})$  constraint is checked by reconstructing the  $\bar{B}^0 \rightarrow D^+\pi^-$  mode among  $\Lambda_c^+\pi^-$  candidates from the region of the invariant mass corresponding to the  $\Lambda_b^0$  signal. The total  $\chi^2$  of this fit is 80.6 for 88 degrees of freedom, corresponding to the fit probability of 70%.

Figure 2 shows the mass fit for the  $D^+\pi^-$  candidates. The large Gaussian peak at  $5.27 \text{ GeV}/c^2$  is the  $\bar{B}^0$  signal. The dashed curve corresponds to the exponential combinatorial background. The dotted curve corresponds to the background from decays of other  $b$  hadrons. The total  $\chi^2$  of this fit is 70.9 for 94 degrees of freedom, corresponding to the fit probability of 96%.

The quantity  $R$  defined in equation (1) is calculated from the signal yield according to

$$R = \frac{N_{\Lambda_b^0}}{N_{\bar{B}^0}} \times \frac{\mathcal{B}(D^+ \rightarrow \pi^+ K^- \pi^+)}{\mathcal{B}(\Lambda_c^+ \rightarrow p K^- \pi^+)} \times \frac{\epsilon(\bar{B}^0)}{\epsilon(\Lambda_b^0)}, \quad (2)$$

where the first factor is the ratio of observed signal yields, the second factor is the ratio of the daughter branching fractions [15], and the third factor is the ratio of reconstruction efficiencies calculated from the Monte Carlo. The signal yields are  $N_{\Lambda_b^0} = 214 \pm 19$  and  $N_{\bar{B}^0} = 790 \pm 32$  respectively. Each reconstruction efficiency is defined for the  $\Lambda_b^0(\bar{B}^0)$  with  $p_T > 6 \text{ GeV}/c$  and  $|\eta| < 1.3$ . The exact configuration of the CDF II detector varied over the course of collecting the data used in the analysis. However, the ratio of reconstruction efficiencies is stable within statistical errors across the different periods of running, with the average value  $\epsilon(\bar{B}^0)/\epsilon(\Lambda_b^0) = 1.65 \pm 0.03$ . From Equation (2) we thus obtain  $R = 0.82 \pm 0.08(\text{stat})$ .

The systematic uncertainty on the measurement of  $R$  is dominated by the error on  $\mathcal{B}(\Lambda_c^+ \rightarrow p K^- \pi^+)$ , yielding a relative error of 27% [15]. Since this uncertainty is independent of our measurement, it is quoted separately. Other sources of systematic uncertainty are the imperfect knowledge of the  $\Lambda_b^0$  lifetime ( $^{+5}_{-4}\%$ ), the production  $p_T$  spectra of both  $\Lambda_b^0$  (7.6%) and  $\bar{B}^0$  (4%), the  $\Lambda_b^0$  polarization (7%), and the  $\Lambda_c^+$  resonant substructure (1%).

The uncertainty due to the finite size of the Monte Carlo samples is 1.9%. The uncertainty due to the difference between the proton and  $\pi^+$  trigger efficiency is 0.6%. The systematic uncertainties due to the background shapes in the invariant mass fits are 4.3% for the  $\Lambda_b^0$  and 0.9% for the  $\bar{B}^0$ . These uncertainties arise from the lack of detailed knowledge of a variety of branching fractions contributing to background shapes that are obtained from the Monte Carlo simulation and fixed in the fit. To evaluate the uncertainty due to these shapes, the branching fractions of the largest decay modes contributing to each of the shapes were varied simultaneously in the simulation, and the shapes were reevaluated. Uncertainties on the mass resolutions of both  $\Lambda_b^0$  and  $\bar{B}^0$ , which are also fixed in the mass fits, contribute 2.8% and 1.8%, respectively. Finally, the contribution of the  $\Lambda_b^0 \rightarrow \Lambda_c^+ K^-$  shape is varied by a factor of 2, contributing 1.6% to the systematic error. The total systematic error excluding the uncertainty on  $\mathcal{B}(\Lambda_c^+ \rightarrow p K^- \pi^+)$  is 13.5%.

A direct comparison with a theoretical prediction of  $R_{BR} \equiv \mathcal{B}(\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-)/\mathcal{B}(\bar{B}^0 \rightarrow D^{(*)+} \pi^-) \approx 1.7$  [5] can be performed if one assumes that  $\sigma(\Lambda_b)$  and  $\sigma(B^0)$  have the same dependence on  $p_T$ , and then use  $f_{\text{baryon}}/f_d$  from high- $p_T$  measurements. From Ref. [15] we obtain  $f_{\text{baryon}}/f_d = 0.25 \pm 0.04$ , which yields  $R_{BR} \approx 3.3 \pm 1.2$ , in agreement with [5].

In summary, we have observed the decay  $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$  for the first time, and measured  $R = 0.82 \pm 0.08(\text{stat}) \pm 0.11(\text{syst}) \pm 0.22(\mathcal{B}_{\Lambda_c^+})$ . The overall error is dominated by the large uncertainty on  $\mathcal{B}(\Lambda_c^+ \rightarrow p K^- \pi^+)$ . The  $\Lambda_b^0 \rightarrow \Lambda_c^+ \pi^-$  sample is the largest  $b$ -baryon sample in existence, and, once augmented by new data, can be used for a variety of other  $\Lambda_b$  measurements, including its lifetime and production properties.

We thank the Fermilab staff and the technical staffs of the participating institutions for their vital contributions.
