HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Search for Diphoton Events with Large Missing Transverse Energy in 7 TeV Proton-Proton Collisions with the ATLAS Detector

The ATLAS Collaboration

A search for diphoton events with large missing transverse energy is presented. The data were collected with the ATLAS detector in proton-proton collisions at $\sqrt{s} = 7$ TeV at the CERN Large Hadron Collider and correspond to an integrated luminosity of 3.1 pb^{-1} . No excess of such events is observed above the Standard Model background prediction. In the context of a specific model with one Universal Extra Dimension with compactification radius R and gravity-induced decays, values of $1/R < 729$ GeV are excluded at 95% CL, providing the most sensitive limit on this model to date.

PACS numbers: 14.80.Rt, 13.85.Rm

In the Standard Model (SM), the production in proton-proton (pp) collisions of diphoton ($\gamma\gamma$) events with large missing transverse energy (E_T^{miss}) is mainly due to $W/Z + \gamma\gamma$ processes. Taking into account the branching ratios of W/Z decays including at least one neutrino, the cross sections are only a few femtobarns for 7 TeV pp collisions. In contrast, some new physics models predict much larger $\gamma\gamma + E_T^{\text{miss}}$ rates. This Letter reports the first $\gamma\gamma + E_T^{\text{miss}}$ search with LHC data, using data recorded with the ATLAS detector. The results are interpreted in the context of a Universal Extra Dimension (UED) model.

UED models [1] postulate the existence of additional spatial dimensions in which all SM particles can propagate, leading to the existence for each SM particle of a series of excitations, known as a Kaluza-Klein (KK) tower. This analysis considers the case of a single TeV^{-1} -sized UED, with compactification radius R . The masses of the states of successive levels in the tower are separated by $\approx 1/R$. For a given KK level, the approximate mass degeneracy of the KK excitations is broken by radiative corrections [2]. The lightest KK particle (LKP) is the KK photon of the first level, denoted γ^* . At the LHC, the main UED process would be production via the strong interaction of a pair of first-level KK quarks and/or gluons [3], which would decay via cascades involving other KK particles until reaching the LKP at the end of the decay chain. If the UED model is embedded in a larger space with N additional eV^{-1} -sized dimensions accessible only to gravity [4], the LKP could decay gravitationally via $\gamma^* \rightarrow \gamma + G$ [5], where G represents one of a tower of eV -spaced graviton states. With two decay chains per event, the final state would be $\gamma\gamma + E_T^{\text{miss}} + X$, where E_T^{miss} results from the escaping gravitons and X represents SM particles emitted in the cascade decays.

The UED model considered is defined by specifying R and Λ , the ultraviolet cut-off used in the calculation of radiative corrections to the KK masses. This analysis treats R as a free parameter and, following the theory calculations [2], sets Λ such that $\Lambda R = 20$. For $1/R = 700$ GeV, the masses of the first-level KK photon, quark

and gluon are 700, 815 and 865 GeV, respectively [6]. The γ^* mass is insensitive to Λ , while other KK masses change by typically a few percent when varying ΛR in the range $10 - 30$. The gravitational decay widths of the KK particles are set by N and M_D , the Planck scale in the $(4 + N)$ -dimensional theory. For the chosen values of $N = 6$ and $M_D = 5$ TeV, and provided $1/R < 1$ TeV, the LKP is the only KK particle to have an appreciable rate of gravitational decay. The same parameter values were used in the only previous study of this model, in which the D0 experiment excluded at 95% CL values of $1/R < 477$ GeV [7].

Monte Carlo (MC) signal samples were produced for a range of $1/R$ values using the implementation [6] of the UED model in PYTHIA [8] version 6.421, and using the MC09 parameter tune [9]. The MC samples were processed through the ATLAS detector simulation [10] based on GEANT4 [11]. In addition to the two high transverse energy (E_T) photons and large E_T^{miss} , the signal events typically include several high- E_T jets due to the cascade decays, with the E_T spectrum of the leading jet peaking at ≈ 100 GeV for $1/R = 700$ GeV.

The ATLAS detector [12] is a multipurpose particle physics apparatus with a forward-backward symmetric cylindrical geometry and nearly 4π solid angle coverage. ATLAS uses a Cartesian right-handed coordinate system, with the nominal collision point at the origin. The anticlockwise beam direction defines the positive z -axis, while the positive x -axis points from the collision point to the centre of the LHC ring and the positive y -axis points upward. The angles ϕ and θ are the azimuthal and polar angles. The pseudorapidity is defined as $\eta = -\ln[\tan(\theta/2)]$. Closest to the beamline are tracking detectors which use layers of silicon-based and straw-tube detectors, located inside a thin superconducting solenoid that provides a 2 T magnetic field, to measure the trajectories of charged particles. The solenoid is surrounded by a hermetic calorimeter system. A liquid-argon (LAr) sampling calorimeter is divided into a central barrel calorimeter and two end-cap calorimeters, each

housed in a separate cryostat. Fine-grained LAr electromagnetic (EM) calorimeters, with excellent energy resolution, provide coverage for $|\eta| < 3.2$. In the region $|\eta| < 2.5$, the EM calorimeters are segmented into three longitudinal layers and the second layer, in which most of the EM shower energy is deposited, is divided into cells of granularity of $\Delta\eta \times \Delta\phi = 0.025 \times 0.025$. A presampler, covering $|\eta| < 1.8$, is used to correct for energy lost upstream of the calorimeter. An iron-scintillator tile calorimeter provides hadronic coverage in the range $|\eta| < 1.7$. In the end-caps ($|\eta| > 1.5$), LAr hadronic calorimeters match the outer $|\eta|$ limits of the end-cap EM calorimeters. LAr forward calorimeters provide both EM and hadronic energy measurements, and extend the coverage to $|\eta| < 4.9$. Outside the calorimeters is an extensive muon system including large superconducting toroidal magnets.

The reconstruction of photons is described in detail in Ref. [13]. To select photon candidates, EM calorimeter clusters were required to pass several quality criteria and to lie outside problematic calorimeter regions. Photon candidates were required to have $|\eta| < 1.81$ and to be outside the transition region $1.37 < |\eta| < 1.52$ between the barrel and the end-cap calorimeters. The analysis uses a “loose” photon selection, which includes cuts on the energy in the hadronic calorimeter as well as on variables that require the transverse width of the shower, measured in the second EM calorimeter layer, to be consistent with the narrow width expected for an EM shower. The loose selection provides a high photon efficiency with modest rejection against the background from jets.

The reconstruction of E_T^{miss} is based on topological calorimeter clusters [14] with $|\eta| < 4.5$ that are seeded by any cell with energy higher than four times its noise level. In an iterative procedure, the cluster grows by including all neighbouring cells with energy higher than twice the noise, plus all cells neighbouring the boundary of this three-dimensional collection. Each cluster is classified as EM or hadronic, depending on its topology, and the cluster energy is calibrated to correct for the non-compensating calorimeter response, energy losses in dead material, and out-of-cluster energies. Events reconstructed with large E_T^{miss} were studied in detail with early data [15]. Rare background events with large transverse energies, unrelated to the collision and concentrated in a few cells, due mainly to discharges and noise, have been observed. Cuts were applied to eliminate such backgrounds, rejecting less than 0.05% of the selected events while having a negligible impact on the signal efficiency.

The data sample was collected during stable beam periods of 7 TeV pp collisions at the LHC, and corresponds to an integrated luminosity of 3.1 pb^{-1} . The events selected had to satisfy a trigger requiring at least one loose photon candidate with $E_T > 20 \text{ GeV}$, and had to contain at least one reconstructed primary vertex consistent with the average beam spot position and with at least

three associated tracks. The trigger and vertex requirements are $\approx 99\%$ efficient for signal MC events. The presence of multiple pp collisions within the same bunch crossing, known as “pileup”, can be analysed by examining N_{vtx} , the number of reconstructed primary vertices in each event. In this data sample, the average value of N_{vtx} was ≈ 2.1 . The MC signal samples included the simulation of pileup and were weighted to match the N_{vtx} distribution observed in data.

Events were retained if they had at least two photon candidates, each with $E_T > 25 \text{ GeV}$. In addition, a photon isolation cut was applied, wherein the E_T in a radius of 0.2 in the η - ϕ space around the center of the cluster, excluding the cells belonging to the cluster in a region corresponding to 5×7 cells in $\eta \times \phi$ in the second layer of the EM calorimeter, had to be less than 35 GeV. This requirement had a signal efficiency greater than 95% but rejected some of the background from multijet events. An event in which each of the two photon candidates satisfied the loose photon cuts was considered a $\gamma\gamma$ candidate event. An independent “misidentified jet” control sample, enriched in events with jets misidentified as photons, was defined as those events where at least one of the photon candidates did not pass the loose photon identification. After all cuts, the $\gamma\gamma$ and misidentified jet samples totaled 520 and 7323 events, respectively. Figure 1 shows the E_T spectrum of the leading photon for the $\gamma\gamma$ candidates and for UED $1/R = 700 \text{ GeV}$ MC events; the UED spectrum extends to much higher E_T values.

FIG. 1. E_T spectrum of the leading photon for the $\gamma\gamma$ candidate sample and for UED $1/R = 700 \text{ GeV}$ MC events (normalized to 100 times the leading order (LO) cross section).

The background was evaluated entirely using data. Non-collision backgrounds, such as cosmic rays and beam-halo events, are reduced to a negligible level by the selection cuts. The main background source, referred to hereafter as QCD background, arises from a mixture of SM processes including $\gamma\gamma$ production, and $\gamma + \text{jet}$ and

multijet events with at least one jet misidentified as a photon. With the loose photon identification, it is expected that $\gamma + \text{jet}$ and multijet events dominate, with only a small $\gamma\gamma$ contribution. The misidentified jet sample provided a model of the E_T^{miss} response for events with jets faking photons. The response for $\gamma\gamma$ events was modeled using the E_T^{miss} spectrum measured in a high purity sample of $Z \rightarrow ee$ events, selected by a combination of kinematic cuts and electron identification requirements [14]. The E_T^{miss} spectrum for $Z \rightarrow ee$ events, which is dominated by the calorimeter response to two genuine EM objects, was verified in MC to model the E_T^{miss} response in SM $\gamma\gamma$ processes, despite their kinematic differences. As shown in Fig. 2, $Z \rightarrow ee$ events typically have somewhat lower E_T^{miss} values than events of the misidentified jet sample, as expected since the presence of jets faking photons should result in a broader E_T^{miss} distribution. The spectrum for the $\gamma\gamma$ candidates, which for low E_T^{miss} is dominated by the QCD background with an unknown mixture of events with zero, one, and two fake photons, lies between these two samples. The E_T^{miss} spectrum of the total QCD background was modeled by a weighted sum of the spectra of the $Z \rightarrow ee$ and misidentified jet samples. The QCD background was normalized to have the same number of events as the $\gamma\gamma$ candidate sample in the region $E_T^{\text{miss}} < 20$ GeV, where any UED signal contribution can be neglected. The relative contributions of the $Z \rightarrow ee$ and misidentified jet samples were determined by fitting the QCD background shape to the E_T^{miss} spectrum of the $\gamma\gamma$ candidates in this same low E_T^{miss} region. The fraction attributed to $\gamma\gamma$ production, as modeled with the $Z \rightarrow ee$ distribution, was determined to be $(36 \pm 22)\%$. The search result is not very sensitive to the exact composition of the QCD background, and the fit error was used to determine systematic uncertainties on the background prediction.

A small additional background results from $W \rightarrow e\nu$ events, which have genuine E_T^{miss} and which can pass the selection if the electron is misidentified as a photon and the second photon is either a real photon in $W\gamma$ events or a jet faking a photon in $W + \text{jets}$ events. A high purity sample of inclusive $W \rightarrow e\nu$ events was selected by a combination of kinematic and electron identification cuts [14]. Requiring in addition a loose photon with $E_T^\gamma > 25$ GeV, a “ $W + \gamma$ ” sample of only 5 events was selected. Accounting for the probability for an electron to be misidentified as a loose photon, as determined using the $Z \rightarrow ee$ sample, the total background contribution due to $W \rightarrow e\nu$ events was then estimated to be only ≈ 0.4 events. Since the number of $W\gamma$ events was too small to measure their E_T^{miss} spectrum, a sample of $W + \text{jets}$ events was used instead, requiring a jet reconstructed with an anti- k_T clustering algorithm [16] with radius parameter 0.4 and $E_T^j > 25$ GeV. The $W(\rightarrow e\nu) + \text{jets}/\gamma$ background contribution was then estimated by normalizing the $W + \text{jets}$ E_T^{miss} spectrum to the expected total

FIG. 2. E_T^{miss} spectra for the $\gamma\gamma$ candidates, for the $Z \rightarrow ee$ and misidentified jet samples used to model the QCD background (each normalized to the number of $\gamma\gamma$ candidates with $E_T^{\text{miss}} < 20$ GeV), and for the $W(\rightarrow e\nu) + \text{jets}/\gamma$ background (normalized to its expected total of ≈ 0.4 events). Variable sized bins are used, and the vertical error bars and shaded bands show the statistical errors.

of ≈ 0.4 events, as shown on Fig. 2.

Figure 3 shows the E_T^{miss} spectrum of the $\gamma\gamma$ candidates, superimposed on the total background prediction, as well as example UED signals. Table I summarizes the number of observed $\gamma\gamma$ candidates, as well as the expected backgrounds and example UED signal contributions, in several E_T^{miss} ranges. The QCD background dominates, and falls steeply with rising E_T^{miss} , while the $W \rightarrow e\nu$ background is very small, and flatter as a function of E_T^{miss} . The UED signals would peak at large values of E_T^{miss} . There is good agreement between the data and predicted background over the entire E_T^{miss} range, with no indication of an excess at high E_T^{miss} values.

The signal search region was chosen to be $E_T^{\text{miss}} > 75$ GeV, before looking at the data, to obtain the best sensitivity to the UED signal. In the signal region, there are zero observed events, compared to an expectation of $0.32 \pm 0.16(\text{stat.})^{+0.37}_{-0.10}(\text{syst.})$ background events. The systematic uncertainty was derived by studying variations of the background determination, including varying within its error the $\gamma\gamma$ fraction determined in the fit of the QCD background, varying the definition of the misidentified jet sample, and eliminating the photon isolation cut.

The UED signal efficiency, determined from MC, increases smoothly from $\approx 43\%$ for $1/R = 500$ GeV to $\approx 48\%$ for $1/R = 700$ GeV, with the lower efficiencies for

TABLE I. The number of observed $\gamma\gamma$ candidates, as well as the SM backgrounds estimated from data and expected UED signal for $1/R$ values of 500 and 700 GeV, given in various E_T^{miss} ranges. The uncertainties are statistical only. The first row, for $E_T^{\text{miss}} < 20$ GeV, is the control region used to normalize the QCD background to the number of observed $\gamma\gamma$ candidates.

E_T^{miss} range (GeV)	Data events	Predicted background events			Expected UED signal events	
		Total	QCD	$W(\rightarrow e\nu) + \text{jets}/\gamma$	$1/R = 500$ GeV	$1/R = 700$ GeV
0 - 20	465	465.0 ± 9.1	465.0 ± 9.1	-	0.28 ± 0.06	0.02 ± 0.01
20 - 30	45	40.5 ± 2.2	40.41 ± 2.17	0.11 ± 0.07	0.45 ± 0.07	0.03 ± 0.01
30 - 50	9	10.3 ± 1.3	10.13 ± 1.30	0.16 ± 0.10	1.60 ± 0.12	0.08 ± 0.01
50 - 75	1	0.93 ± 0.23	0.85 ± 0.23	0.08 ± 0.05	2.84 ± 0.16	0.14 ± 0.01
> 75	0	0.32 ± 0.16	0.28 ± 0.15	0.04 ± 0.03	40.45 ± 0.62	4.21 ± 0.06

FIG. 3. E_T^{miss} spectrum for the $\gamma\gamma$ candidates, compared to the total SM background as estimated from data. Also shown are the expected UED signals for $1/R = 500$ GeV and 700 GeV. Variable sized bins are used, and the vertical error bars and shaded bands show the statistical errors.

smaller $1/R$ due mostly to the $E_T^{\text{miss}} > 75$ GeV definition of the signal region. The various relative systematic uncertainties on the extraction of the UED signal cross section are summarized in Table II, including the dominant 11% uncertainty on the integrated luminosity [17]. Uncertainties on the efficiency for reconstructing and identifying the $\gamma\gamma$ pair arise mainly due to differences between MC and data in the distributions of the photon identification variables, the need to extrapolate to the higher E_T values (see Fig. 1) typical of the UED photons, the impact of the photon quality cuts, varying the scale of the photon E_T cut, and uncertainties in the detailed material composition of the detector. Together these provide a systematic uncertainty of 4%. The influence of pileup, evaluated by comparing MC samples with and without pileup, gives a systematic uncertainty of 2%. Systematic

effects on the E_T^{miss} reconstruction [14], including pileup, varying the cluster energies within the current uncertainties, and varying the expected E_T^{miss} resolution between the measured performance and MC expectations, combine to give a 1% uncertainty on the signal efficiency. Finally, the 1% statistical error on the signal efficiency as determined by MC is treated as a systematic uncertainty on the result. Adding in quadrature, the total systematic uncertainty on the signal yield is 12%.

TABLE II. Relative systematic uncertainties on the expected UED signal yield. For more details, see the text.

Source of uncertainty	Uncertainty
Integrated luminosity	11%
Photon reconstruction and identification	4%
Effect of pileup	2%
E_T^{miss} reconstruction and scale	1%
Signal MC statistics	1%
Total	12%

Given the good agreement between the measured E_T^{miss} spectrum and the expected background, a limit was set on $1/R$ in the specific UED model considered here. A Bayesian approach was used to calculate a limit based on the number of observed and expected events with $E_T^{\text{miss}} > 75$ GeV. A Poisson distribution was used as the likelihood function for the expected number of signal events, and a flat prior was used for the signal cross section. Log-normal priors were used for the various sources of uncertainty, which were treated as nuisance parameters. It was verified that the result is not very sensitive to the detailed form of the assumed priors. Figure 4 depicts the resulting 95% CL upper limit within the context of the UED model considered, together with the LO UED cross section as a function of $1/R$. The LO cross section was used since higher order corrections have not been calculated for the UED model. An uncertainty on the signal cross section due to parton distribution functions (PDF) was determined by comparing the predictions using MRST2007 [18] PDF's with those from the full set of error PDF's of CTEQ6.6 [19]. The resultant uncertainty, namely $\pm 8\%$ essentially independent of $1/R$, is shown by the width of the theory curve band. The observed 95%

CL exclusion region is $1/R < 729$ GeV. The result depends weakly on the systematic uncertainties, and would only increase to 732 GeV if they were neglected. Changing the E_T^{miss} cut to 60 or 90 GeV would change the limit by only a few GeV. A cross check using a higher purity $\gamma\gamma$ sample, achieved by requiring that both photons pass tighter identification cuts that reject more of the background from jets, produced a consistent result.

FIG. 4. 95% CL upper limits on the UED production cross section, and the LO theory cross section prediction, as a function of $1/R$. The shaded band shows the PDF uncertainty.

In conclusion, a search for $\gamma\gamma$ events with large E_T^{miss} , conducted using a 3.1 pb^{-1} sample of 7 TeV pp collisions recorded with the ATLAS detector at the LHC, found no evidence of an excess above the SM prediction. The results were used to set limits on a specific model with one UED and gravity-induced LKP decays, excluding at the 95% CL values of $1/R < 729$ GeV, and significantly surpassing the only existing experimental limit [7] on this model.

We wish to thank CERN for the efficient commissioning and operation of the LHC during this initial high-energy data-taking period as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

- ¹⁸⁶ RHIC and ATLAS Computing Facility, Physics Department, Building 510, Brookhaven National Laboratory, Upton, New York 11973, United States of America
- ^a Also at LIP, Portugal
- ^b Also at Faculdade de Ciencias, Universidade de Lisboa, Portugal
- ^c Also at CPPM, Marseille, France.
- ^d Also at Centro de Fisica Nuclear da Universidade de Lisboa, Portugal
- ^e Also at TRIUMF, Vancouver, Canada
- ^f Also at FPACS, AGH-UST, Cracow, Poland
- ^g Now at Universita' dell'Insubria, Dipartimento di Fisica e Matematica
- ^h Also at Department of Physics, University of Coimbra, Portugal
- ⁱ Now at CERN
- ^j Also at Università di Napoli Parthenope, Napoli, Italy
- ^k Also at Institute of Particle Physics (IPP), Canada
- ^l Also at Università di Napoli Parthenope, via A. Acton 38, IT - 80133 Napoli, Italy
- ^m Louisiana Tech University, 305 Wisteria Street, P.O. Box 3178, Ruston, LA 71272, United States of America
- ⁿ Also at Universidade de Lisboa, Portugal
- ^o At California State University, Fresno, USA
- ^p Also at TRIUMF, 4004 Wesbrook Mall, Vancouver, B.C. V6T 2A3, Canada
- ^q Also at Faculdade de Ciencias, Universidade de Lisboa, Portugal and at Centro de Fisica Nuclear da Universidade de Lisboa, Portugal
- ^r Also at FPACS, AGH-UST, Cracow, Poland
- ^s Also at California Institute of Technology, Pasadena, USA
- ^t Louisiana Tech University, Ruston, USA
- ^u Also at University of Montreal, Montreal, Canada
- ^v Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg, Germany
- ^w Now at Chonnam National University, Chonnam, Korea 500-757
- ^x Also at Institut für Experimentalphysik, Universität Hamburg, Luruper Chaussee 149, 22761 Hamburg, Germany
- ^y Also at School of Physics and Engineering, Sun Yat-sen University, China
- ^z Also at Taiwan Tier-1, ASGC, Academia Sinica, Taipei, Taiwan
- ^{aa} Also at School of Physics, Shandong University, Jinan, China
- ^{ab} Also at California Institute of Technology, Pasadena, USA
- ^{ac} Also at Rutherford Appleton Laboratory, Didcot, UK
- ^{ad} Also at school of physics, Shandong University, Jinan
- ^{ae} Also at Rutherford Appleton Laboratory, Didcot, UK
- ^{af} Also at TRIUMF, Vancouver, Canada
- ^{ag} Now at KEK
- ^{ah} Also at Departamento de Fisica, Universidade de Minho, Portugal
- ^{ai} University of South Carolina, Columbia, USA
- ^{aj} Also at KFKI Research Institute for Particle and Nuclear Physics, Budapest, Hungary
- ^{ak} University of South Carolina, Dept. of Physics and Astronomy, 700 S. Main St, Columbia, SC 29208, United States of America
- ^{al} Also at Institute of Physics, Jagiellonian University, Cracow, Poland
- ^{am} Louisiana Tech University, Ruston, USA
- ^{an} Also at School of Physics and Engineering, Sun Yat-sen University, Taiwan
- ^{ao} University of South Carolina, Columbia, USA
- ^{ap} Transfer to LHCb 31.01.2010
- ^{aq} Also at Oxford University, Department of Physics, Denys Wilkinson Building, Keble Road, Oxford OX1 3RH,

United Kingdom

ar Also at school of physics and engineering, Sun Yat-sen University

as Also at CEA

at Also at LPNHE, Paris, France

au Also at Nanjing University, China
